ABSTRACT

Investigations of the Bystrzyca River, its tributaries and the Zemborzyckie Lake concerned physico-chemical water qualities, degrees of saprogenicity, classes of water purity and biocenosis-fishery assessment and were carried out on the basis of the structure of ecological communities of zooplankton, zoobenthos and neoton. In some river sections, the water was recorded to belong to the third class of water purity or was even too polluted to be included in this class, and the pollution brought about significant changes in zoocenoses. The reservoir's water contained a high content of total suspended matter, phosphorus and nitrogen. Pike, which was the dominant species after the construction of the reservoir, has recently been replaced by bream and pike-perch.
